(54) Title: METHODS FOR THE COLD EXTRUSION OF METALLIC ELEMENTS WITH DEAD OR THROUGH HOLES AND PLANT FOR CARRYING OUT SAID METHODS

(57) Abstract: Cold extrusion procedures for obtaining metal elements such as for example bushings, nuts or other elements with dead or through holes, screws, standard and special shape extruded or pressed products, etc. on a machining centre comprising a series of hydraulic presses connected to each other with an automatic movement system. The final drilling or shearing of the elements is advantageously carried out by a dedicated drilling or shearing unit, working at high speed, which can consist of a vertical mechanical press. The use of the plant comprising several hydraulic presses together with the rapid drilling or shearing unit makes it possible to achieve a high level of productivity.

METHODS FOR THE COLD EXTRUSION OF METALLIC ELEMENTS WITH DEAD
OR THROUGH HOLES AND PLANT FOR CARRYING OUT SAID METHODS

TECHNICAL FIELD

10 The present invention concerns procedures for the cold
extrusion on hydraulic presses of metal elements.

More specifically, the present invention refers to cold
extrusion procedures for the production of metal elements
such as for example bushings, nuts or other elements with
15 dead or through holes, screws, standard and special shape
extruded or pressed products, etc.

These cold extrusion procedures can be carried out by
means of a plant comprising a series of hydraulic presses
connected to each other with an automatic movement system
20 and the resulting products generally consist of bushings,
nuts or other elements with dead or through holes, screws,
standard and special shape extruded or pressed products,
etc. made from steel, regardless of the type and resistance
class of the steel, or from other metal materials
25 (aluminium, copper, brass) with an external diameter
indicatively greater than 30 mm.

The present invention can be applied in the mechanical
industry sector for the production of medium-high quantity
batches.

30

BACKGROUND ART

It is known that the production of tubular metal elements such as, for example, bushings substantially takes place according to four possible procedures:

- cold pressing using horizontal mechanical presses;
- 5 - cold or hot pressing using vertical mechanical presses and subsequent lathe machining;
- turning of a previously rolled tube;
- removal of shavings starting from a full blank.

10 Cold pressing using multistation horizontal presses foresees the absorption of a considerable pressing power to achieve a thrust of around 1200 tons necessary to carry out the machining. These horizontal presses involve a very high investment cost to achieve a high level of productivity which can reach 40 pieces a minute.

15 The great speed of the machining process, consisting substantially of an extrusion operation, causes an increase in the temperature of the piece which can exceed 700 degrees. This temperature exceeds the tempering temperature of all the types of steel used to construct extrusion tools
20 and punches with evident problems regarding the short life of these instruments. Experience shows that this problem is very evident above all in the pressing of pieces with a diameter greater than 30 mm.

Another disadvantage is represented by the fact that
25 the tolerances relative to the longitudinal dimensions of the pieces are extremely high, at least as regards parts which require a certain precision, such as for example the bushings used for connecting rods which require tolerances of around 0.3 mm.

30 As far as single-station vertical presses are concerned, the production procedure for tubular elements

foresees pressing in subsequent but not sequential phases, to achieve the various deformation stages of the piece.

Between one stage and the next, due to the considerable work hardening of the fibres of the rough-shaped material, it is necessary to carry out several heat treatment cycles consisting substantially of annealing.

One disadvantage is represented by the fact that this sequence of treatments has a considerable effect on the pieces as well as requiring, for each stage, lubrication of the pieces (phosphate coating) which prolongs the overall time needed to obtain the finished piece.

Another drawback is represented by the fact that, in this case too, it is extremely difficult to maintain the tolerances and the life of the tools is totally unsatisfactory again because of the high machining speed.

This processing by means of single-station vertical presses also requires final turning with a further increase in costs.

As far as hot pressing is concerned, maintaining the required tolerances and tool wear represent even more serious problems than those foreseen in the previous machining processes making this procedure uncompetitive, due also to a final stage on machine tools.

As regards rolled tube turning, this is the most commonly used procedure for bushings with an external diameter less than or equal to 50 mm. The tube, rolled by the steel works in 3-5 metre bars, is cut to size and transported to a machining centre which, by removal of the shavings, forms the external radii and the two entrances.

One drawback is represented by the fact that the raw material forming the tube costs 60-70% more than the 'full'

steel that can be used in the other processes described above.

As regards turning starting from a blank, this process is used for bushings with an external diameter greater than 50 mm, rolled tubes of these dimensions not being available on the market.

This procedure requires the use of automatic lathes which produce pieces with a good frequency (approx. 1 every 30 seconds).

One disadvantage is represented by the fact that there is a very high rate of material wastage: around 50-55% of the original blank.

Another procedure for obtaining tubular elements consists of drawing, starting from a flat piece which is then deformed and finally finished on the machine tools.

In this case too the fibres of the material undergo considerable work hardening, altering and degrading the mechanical features of the finished product.

There is also a very high rate of production rejects, considerably increasing the costs of the finished product.

The patent US-A-6098436 (Girardello) describes a method for the machining of metals to obtain tubes of different dimensions and for different uses, made from steel with a carbon content of between 0.10% and 0.50%, with strict tolerances.

This method foresees the use, as a starting material, of a round bar of hot rolled steel which is then cut in order to obtain at least one block which is drilled and subjected to chemical treatment. The block is then pressed and, if necessary, subjected to final turning and a heat treatment in order to obtain a finished product such as a

hydraulic or oleopneumatic cylinder or a container for high pressure filters or a tube for high pressure, or a bearing, using a limited quantity of steel.

5

DESCRIPTION OF THE INVENTION

This invention proposes to provide a first procedure for obtaining metal elements such as for example bushings, nuts or other products with dead or through holes, etc., which can eliminate or significantly reduce the drawbacks described above.

10

This invention also proposes to provide a second procedure for obtaining metal elements such as for example screws, standard or special shape extruded or pressed products, etc., with a diameter greater than 30 mm, which can be easily produced in order to be economically advantageous.

15

According to a first aspect, the procedure for obtaining tubular metal elements such as for example bushings, nuts or other products with dead or through holes, etc., according to the invention, foresees:

20

- setting up and preparation of a blank in rolls or bars of full metal material;
- straightening in the case of rolls and cutting of the metal material into pieces of a determined length;
- 25 - pressing in sequence achieved by passing these pieces sequentially through a number of hydraulic presses in order to obtain a blank presenting one or two dead holes longitudinally opposite each other separated by a central transverse section;
- 30 - in some cases, for products with through holes, the drilling of the central transverse section can be

achieved by the action of a mechanical press.

According to a second aspect, the procedure for obtaining metal elements such as for example screws, standard or special shape extruded or pressed products, etc., with a diameter indicatively greater than 30 mm, according to this invention, comprises:

- setting up and preparation of a blank in rolls or bars of full metal material;
- straightening and in the case of rolls and cutting of the metal material into pieces of a determined length;
- pressing in sequence achieved by passing these pieces sequentially through a number of hydraulic presses in order to obtain a series of blanks;
- if necessary, shearing which, for hexagonal-head screws for example, can be achieved through the action of a mechanical press.

According to the invention, both procedures consist of sequential cold pressing on a number of hydraulic presses of sections of steel or other material to obtain pieces of various shapes and sizes with diameters indicatively greater than 30 millimetres.

Advantageously the setting up and preparation of the blank differ according to the material used.

The plant used advantageously consists of a number of hydraulic presses connected by means of a transfer unit designed to move the pieces being machined. The transfer unit comprises a series of manipulator gripper robots powered by a hydraulic, mechanical or pneumatic source of energy as necessary.

The drilling or shearing are advantageously carried out by the intervention of a dedicated drilling or shearing

unit, working at high speed, which can consist of a vertical mechanical press.

The use of the plant consisting of several hydraulic presses together with the rapid drilling or shearing unit
5 allows a high level of productivity.

DESCRIPTION OF THE DRAWINGS

Other features and advantages of the invention will become evident on reading the following description of a
10 form of embodiment of the invention, given as a non-binding example, with the help of the enclosed drawings, in which:

- figure 1 shows an elevated side view of a straightening unit to be applied if rolls are used, and an example of a cutting unit to carry out part of the procedure
15 according to the invention;
- figure 2 shows an elevated front view partially in cross-section of a hydraulic press which together with other identical or similar hydraulic and/or mechanical presses form a work centre for carrying out the
20 procedures according to the invention;
- figure 3 represents an elevated front view of the progressive configuration of a bushing during the pressing stage;
- figure 4 represents a schematic side view partially in
25 cross-section of a plant comprising a plurality of presses according to the invention;
- figure 5 represents a schematic plan view of a plant comprising a plurality of presses according to the invention.

DESCRIPTION OF ONE EMBODIMENT OF THE INVENTION

The procedures for obtaining metal elements according to the invention comprise both the setting up and preparation of a blank in rolls or bars of full metal material of various shapes such as for example round, square, rectangular, etc., the straightening in the case of rolls and the cutting of the metal material into pieces of a determined length.

The procedure for obtaining drilled elements such as for example bushings, nuts or other elements with dead or through holes etc. then foresees the pressing in sequence achieved by passing these pieces sequentially through a number of hydraulic presses in order to obtain a series of blanks each of which can present one or two dead holes longitudinally opposite each other separated by a central transverse section; in some cases, for products with through holes, the drilling of the central transverse section can be achieved by the action of a mechanical press.

According to the invention, the material initially in rolls or in bars is prepared in different ways depending on the initial chemical composition of the material.

In particular the preparation cycles can differ according to whether the material is stainless steel (or steel in any case containing high percentages of chrome and nickel) or a low-alloy steel typically casehardened or hardened and tempered or subjected to other specific cycles depending on the raw material specifically requested by the customer.

In the first case the material is advantageously treated by solution annealing and pickled in a balanced solution of sulphuric acid, hydrofluoric acid, potassium

permanganate and hydrogen peroxide.

The material is then washed repeatedly by means of immersion in a salting tank in order to facilitate the pressing.

5 If a low-alloy steel is used, the material is pickled in sulphuric acid for 10 to 15 minutes and then washed by immersion in a phosphating tank in which, by chemical reaction, a layer of zinc phosphate is created on the surface of the piece.

10 On completion of this stage the material is washed again by immersion in a sodium stearate tank where, again by chemical reaction, a thin layer of zinc stearate forms on top of the previous layer of zinc phosphate.

Other specific cycles can be carried out, according to
15 the raw material specifically requested by the customer, and adapted to the new process as per this invention.

If a roll is used, the previously washed metal material is straightened by loading it on a wire-straightening unit designed to unroll the skein. The free end of the roll is
20 pulled through a first set of rollers and then through a system of opposite rollers designed to straighten the wire and transfer it to a cutting unit.

The material is then cut into pieces of a predetermined length by a number of possible procedures such as for
25 example mechanical or hydraulic processes by means of one or more mobile blades or in the traditional way by a circular saw which acts in synchronisation with the previously described wire-straightening units in the case of rolls.

With reference to figures 4 and 5, the pieces of
30 material to be machined constitute the blanks to be transferred to a pressing unit consisting of a machining

centre 30 comprising, for example, a series of hydraulic presses 31, 32, 33, 34, 35.

Each individual press can be equipped with the power to guarantee the thrust necessary for the cold extrusion of the blanks and the system for the approach and upward movement of the punch will have an extremely high speed in order to increase the productivity of the machining centre.

In order to move the pieces from one press to another the procedure foresees the use of a transfer unit which can consist of a series of manipulator robots 41, 42, 43, 44, 45 comprising steel grippers 50 connected together and powered by a hydraulic, mechanical or compressed-air device as required.

The individual grippers 50 can transfer each blank from one press to another and, if required by the pressing cycle, rotate the blank at various angles during the transfer.

The individual stations of the plant consisting of a plurality of presses 30 can be equipped with extraction units, in their lower part near the bed face and near the pressing cylinder. These extraction units can consist of small hydraulic linear actuators or another mechanical or pneumatic system as required.

The functioning and synchronisation of the individual presses and of the transfer unit are advantageously controlled by a PLC or a microprocessor as necessary.

It is also possible to equip the plant with a mechanical drilling or shearing unit 60 consisting, for example, of a vertical mechanical press, working from the bottom upwards or vice versa, as required.

In the case of drilled products the punch of this press is designed to eject the transverse section or plug from the

blank, which was left by the previous pressing and extrusion stage carried out on the machining centre by the various hydraulic presses.

In the case of sheared products, the shearing die of this press is designed to eject the excess material from the blank which was left by the previous pressing and extrusion stage carried out on the machining centre.

Advantageously, the drilling or shearing unit 60 can be equipped with wheels so that it can be moved and applied indifferently to each pressing station from which the hydraulic extraction cylinder can be easily removed.

With reference to figure 1, which refers to starting material in roll form, it can be noted that the blank 10 consisting of a full bar, once unrolled from a skein (not shown in the drawings), is pulled through trains of opposite rollers 11 designed to straighten the material.

The bar in this example of a full rod 10 is then pulled towards a cutting unit, for example consisting of a circular saw 12, which produces sections that can be subsequently processed by the machining centre consisting of a number of hydraulic presses.

As can be seen in figure 2, one station 31 of the machining centre consists of a block 14 housing a hydraulic piston 15 which carries out the pressing operation. Inside the hydraulic piston 15 is an extraction piston 16 facing a die bed 17.

The lower part of the die bed 17 is equipped with an extraction unit 18 designed to move the blanks.

With reference to figure 3, the blank to be machined 10, is gradually deformed (represented in the figure from left to right) in order to form two longitudinally opposite

dead holes 19 separated by a transverse section or plug 20 which can subsequently be removed by means of a drilling unit (not shown in the drawings).

5 The invention is described above with reference to a particular form of embodiment, consisting of the pressing of tubular metal elements, such as bushings, nuts or other elements with dead or through holes or the like.

10 It is nevertheless clear for the technical expert that the plant as described above can easily be adapted to obtain full pieces such as screws, or special shape extruded or pressed products, and to obtain any standard shape extruded or pressed products, whether drilled or sheared, according to machining requirements, which follow the construction specifications dictated by the various international
15 standards for fasteners or fixing systems such as for example the DIN, ISO, ASTM, ANSI/ASME, JIS and SAE standards, etc., and in general to any mechanical element that can be cold pressed or extruded on the basis of a drawing provided by the customer and with a diameter
20 indicatively greater than 30 mm.

CLAIMS

1. Procedure for the cold processing of tubular metal elements or other elements with dead or through holes, nuts or similar, comprising the following machining stages:

- setting up and preparation of a blank (10) in rolls or bars of full metal material;
- straightening in the case of rolls and cutting of the metal material (10) into pieces of a determined length;
- pressing in sequence achieved by passing these pieces sequentially through a plurality of work stations (31) of a work centre consisting of several presses in order to obtain a blank element presenting one or two longitudinally opposite dead holes (19) separated by a central transverse section (20);
- the through drilling of the blank by removal of this central traverse section (20).

2. Procedure for the cold processing of metal elements such as standard and special shape extruded or pressed screws, etc., comprising the following machining stages:

- setting up and preparation of a blank (10) in rolls or bars of full metal material;
- straightening, in the case of rolls, and the cutting of this metal material (10) into pieces of a determined length;
- pressing in sequence achieved by passing these pieces sequentially through a plurality of work stations (31) of a multi-press plant in order to obtain a finished element (20) with or without swarf

or waste.

3. Procedure according to any one of the claims 1 and 2, in which the setting up and preparation of the full blank (10) differs according to the metal material used.

5 4. Procedure according to claim 3, carried out on material consisting of stainless steel, characterised in that the stainless steel is initially treated by solution annealing and pickled in a balanced solution of sulphuric acid, hydrofluoric acid, potassium permanganate and hydrogen peroxide, and subsequently
10 washed repeatedly by means of immersion in a salting tank in order to facilitate the pressing.

5. Procedure according to claim 3, carried out on material consisting of low-alloy steel, characterised in that
15 this material is pickled in sulphuric acid and subsequently washed in a phosphating tank in which, by chemical reaction, a layer of zinc phosphate is created on the surface of the piece, then immersed in a sodium stearate tank where, again by chemical reaction, a thin
20 layer of zinc stearate forms on top of the previous layer of zinc phosphate.

6. Procedure according to claim 2, characterised in that the products undergo shearing, for example for hexagonal-head screws, which can be carried out by means
25 of a mechanical press.

7. Procedure according to any one of the claims from 2 to 6, carried out on starting material in the form of rolls, in which the previously washed metal material is straightened by loading it on a wire-straightening unit designed to unroll the skein.
30

8. Procedure according to any one of the claims from 2 to

6, carried out on starting material in the form of bars, in which these bars are loaded in bundles in a bar sectioning plant and in which the bars are presented at the cutting station in a synchronised way according to the needs of the machining centre consisting of the presses.

9. Procedure according to claim 7, in which the free end of the roll is pulled through a first set of rollers and then through a system of opposite rollers designed to straighten the wire and transfer it to a cutting unit.

10. Procedure according to any one of the claims 8 and 9, in which the material is cut into pieces of a predetermined length, advantageously by various possible procedures such as for example mechanical or hydraulic processes by means of one or mobile blades or by a circular saw.

11. Procedure according to any one of the preceding claims, characterised in that the plant or machining centre (30) consists of a series of hydraulic presses of various sizes and power levels (31-34) connected by a transfer unit designed to move the pieces (10) being machined.

12. Procedure according to claim 11, characterised in that the transfer unit consists of a series of gripper units (40-44) powered by an appropriate source of energy.

13. Procedure according to any one of the preceding claims, characterised in that the drilling or shearing is carried out by a special unit consisting of a vertical press.

14. Procedure according to claim 13, characterised in that this vertical press consists of a mechanical press.

15. Procedure according to any one of the preceding claims characterised in that the functioning and

synchronisation of the individual presses and of the transfer unit are controlled by a PLC or a microprocessor.

5 16. Plant for the implementation of a procedure according to any one of the preceding claims, characterised in that it comprises a series of hydraulic presses adjacent to each other, designed to carry out a successive series of pressing operations on pieces to be machined which are transferred from one press to another by means of
10 appropriate automated manipulators.

17. Plant according to claim 16, characterised in that it also comprises a drilling or shearing station.

15 18. Plant according to claim 17, characterised in that this drilling or shearing station consists of a vertical mechanical press.
